Abstract

A set of 54 test examples is presented for a very general class of feasibility problems that involve expensive function evaluations, e.g. simulation runs. The presence of expensive functions is artificially introduced by defining parts or complete problems as expensive. These examples are adapted from the CUTEr test set [1].

Keywords: feasibility problem, nonlinear system, derivative-free, expensive function, test set

1 Introduction

Simulations have become a fundamental tool in the academic world as well as in industry over the past years. Especially engineering applications benefit from the rising number of simulation tools for a large variety of applications. One of the major goals of these simulations is the improvement of the simulated processes, which leads to several kinds of simulation-based problems in optimization. In this paper, we consider feasibility problems, i.e. nonlinear systems of equations and inequalities.

As simulations are in many applications very time consuming and do usually not provide derivative information, they can be considered as so called expensive functions. Specialized solution algorithms for such problems have to use as few evaluations of the expensive functions, e.g. simulation runs, as possible. Usually the cost of one evaluation of the expensive function, i.e. the computation time or the cost for a single simulation run or experiment, is dominating the total cost of the algorithm. Hence it is reasonable to compare different algorithms for problems with expensive functions in terms of the number of evaluations of the expensive functions.

In this paper we present a set of 54 test problems of a very general class of feasibility problems involving one or several expensive functions of the form

\begin{equation}
\begin{align*}
    c_E(x, u(x)) &= 0 \\
    c_I(x, u(x)) &\leq 0,
\end{align*}
\end{equation}
where \( u : \mathbb{R}^n \rightarrow \mathbb{R}^m \) is an expensive function, which is assumed to be smooth, and 
\( c_E : \mathbb{R}^{n+m} \rightarrow \mathbb{R}^p \) and \( c_I : \mathbb{R}^{n+m} \rightarrow \mathbb{R}^q \) are smooth "cheap" functions, i.e. \( c_E \) and \( c_I \) are explicitly given or fast and cheap to evaluate. This nested function formulation provides the possibility of modeling as much known information of a given process as available within the outer functions \( c_E \) and \( c_I \). Numerical tests have shown that, in general, the more information is provided in the outer functions, the less function evaluations of the expensive function are necessary [3].

2 Set of test examples

The following set of 54 test problems is based on a subset of the test problems in the CUTEr collection [1] and is inspired by the selection of test problems for FILTRANE, a nonlinear feasibility problem solver [2]. The test problems are selected to represent different function types and reasonable problem sizes. Since many engineering applications only have a small number of variables (often called design variables) and a small number of outcomes of the expensive function, we have mainly chosen test problems with less than 10 variables, but also problems up to 100 variables are included. Some problems are scalable and can therefore easily be transformed to have a larger number of variables. Some reasonable values are included in the concerned problem descriptions depending on the suggestions in [1].

None of the available test problems in the CUTEr collection with an appropriate problem size contains inequalities. Thus, we have redefined some equations as inequalities to obtain a well-balanced and significant test set for problems of the form (1).

To simulate the presence of one or more expensive functions, some parts of the nonlinear systems of equations are defined to be expensive. The advantage of simple functions as being artificially expensive instead of using 'real' expensive functions is the much faster solution time of the test examples. Thus, larger test series like parameter tests can be executed to a greater extend. Counting the number of evaluations of the expensive function then provides information on the expected execution time for practical applications.

In Table 1, we give an overview over the test problems which were taken from the CUTEr collection and the corresponding modifications. The problems names that are listed below are adapted from the corresponding problems in the CUTEr test set in [1]. Besides the problem dimensions and the number of equations and inequalities, the table also contains information about the specific choice of the expensive function(s) we use in the corresponding problems. This information is provided in the rows 'Ex.func.' in Table 1 in the following way:

- The first character gives the number of expensive functions in the particular problem.
- The second character specifies the type of the expensive function. The expensive function can be:
E exponential
H hyperbolic
L logarithmic
P polynomial
T trigonometric
X of type $x^x$

If more than one of these types are involved, all of them are mentioned.

- The third character provides information on the occurrence of the expensive function in the overall system:

A at least one part in every equation or inequality is considered as expensive
C the complete system is considered as expensive
E entire equations or inequalities are considered as expensive
O only parts in some equations or inequalities are considered as expensive

In addition to the descriptions of the feasibility problems, a starting point is given for all problems as well as suggestions for parameter choices, if necessary. These information are also based on those for the corresponding problems in [1].

    c_2 : u_2 &= 0
\end{align*}

with the expensive functions

\begin{align*}
    u_1 &= 100(x_2 - \sin(x_1)) \\
    u_2 &= \frac{x_1}{2}
\end{align*}

**Problem 54:** Zangwil3\_exp

\begin{align*}
    c_1 : u_1 &= 0 \\
    c_2 : u_2 &= 0 \\
    c_3 : u_3 &= 0
\end{align*}

with the expensive functions

\begin{align*}
    u_1 &= x_1 - x_2 + x_3 \\
    u_2 &= -x_1 + x_2 + x_3 \\
    u_3 &= x_1 + x_2 - x_3
\end{align*}

and an initial point $\bar{x} = (100, -1, 2.5)$.
